Introduction

Latent variables

Introduction

Latent variables

- Variables that cannot be directly observed \rightarrow Latent variables (e.g., Intelligence)
- Inferred from directly observed indicators → Observed variables (e.g., the response to the Raven's matrices)
- Operazionalization of the latent variable is crucial

Latent variables

Let's say we have a friend, Giorgio, and after observing what he does usually, we see that:

- He has a lot of friends
- He feels comfortable in social situations involving many people
- He goes the extra mile to stay in touch with people
- . . .

Giorgio's behaviors (**observed variables**) can be explained by considering the latent variable *extraversion*

Modelling latent variables

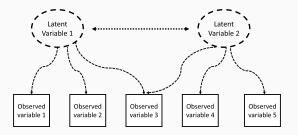

Introduction

Modelling latent variables

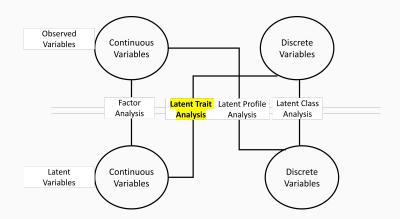

The latent variablesmust be linked to the observed variables \rightarrow mathematical and statistical models

Assumptions:

- The latent variables are the underlying cause of the observed variables
- Local independence: The correlation between the observed variables after controlling for the influence of the latent variable

Modelling latent variables

IRT models and Rasch model \rightarrow Models for latent trait

IRT vs. CTT

Introduction

IRT vs. CTT

IRT vs. CTT

IRT models and Classical Test Theory (CTT) models have the same aim \rightarrow "measuring" people \rightarrow locate the position of each person on a latent trait

IRT

CTT

Focus \rightarrow Items

 $\mathsf{Focus} \to \mathsf{Test}$

Introduction

Basics of IRT

The probability of an observed response (observed variable) depends on the characteristics of both the person and the item

The characteristics of the person can be described by a parameter of the person \rightarrow latent trait (e.g., intelligence, self-esteem, extroversion etc.)

The characteristics of the item can be described by one or more parameters, (difficulty, discrimination, guessing, careless error)

The item, the person and their characteristics are located on the same latent trait

Q1
$$3 + 2 = ?$$
 d_{Q1}

Q1 Q2
$$3+2=?$$
 $3x-2y+4=?$ d_{Q1} d_{Q2}

 A_{Bart}

Different IRT models according to:

- 1 Latent trait:
- Unidimensional model
- Multidimensional model
- Response categories:
- Dichotomous items (Two response categories, e.g., true/falso, agree/disagree)
- Polytomous items (at least 3 response categories, e.g., Likert-type scale)

These models can be distinguinshed according to the number of parameters describing the charcateristics of the items.

- One-Parameter Logistic Model (1-PL)
- Two-Parameter Logistic Model (2-PL)
- Three-Parameter Logistic Model (3-PL)
- Four-Parameter Logistic Model (4-PL)

- Person and items parameters are on the same latent trait
- As the distance on the latent trait between the person parameter and the item parameter increases, the probability of a correct response changes
- When the parameter of the person matches the parameter of the item, then the probability of observing a correct response is 50% (Only for the 1-PL)

1-PL

Item Response Function

1-PL

Item Response Function

Item Response Function

The probability that person p responds correctly to item i is formalized ad

$$P(x_{pi} = 1 | \theta_p, b_i) = \frac{\exp(\theta_p - b_i)}{1 + \exp(\theta_p - b_i)}$$

 θ_p : Ability of the person (i.e., latent trait level of the person) \to The value of θ_p , the higher the amount of latent trait of p

 b_i ; difficulty of item i (location of the item on the latent trait) \rightarrow The higher the value of b_i , the most difficult the item is

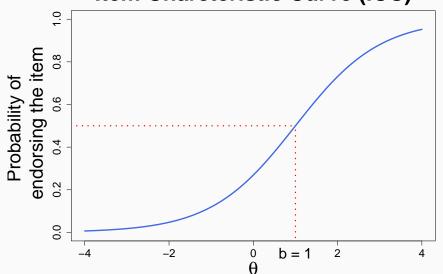

Item Charcteristic Curve

1-PL

Item Charcteristic Curve

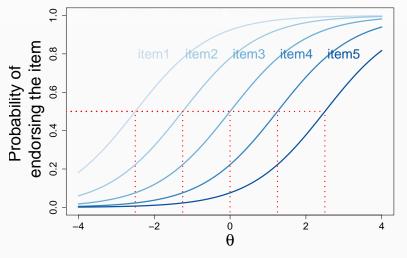

Item Charcteristic Curve

Item Charcteristic Curve (ICC)

Item Charcteristic Curve

ICC - Different locations

	item1	item2	item3	item4	item5
b	-2.50	-1.25	0.00	1.25	2.50

1-PL

Item Information Function

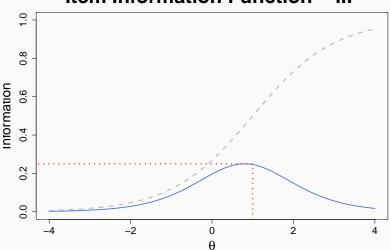

Measure of the precision with which the item assesses different levels of the latent trait \rightarrow *Item Information Function*:

$$I_I = P_i(\theta, b_i)Q_i(\theta, b_i)$$

 $Q=1-P_i(heta_p,b_i)$ is the probability of choosing the incorrect response

The IIFis maximized when
$$\theta_p=b_i \to P(x_{pi}=1)=P(x_{pi}=0)=0.50 \to I_i=.25$$

Item Information Function – IIF

The item is mostly informative for subjects with a latent trait level close to the location of the item \rightarrow the higher the distance between the latent trait level of the person and the location of the item, the lower the IFF

High variability in the latent trait levels of the respondents \to items with locations spread along the entire latent trait

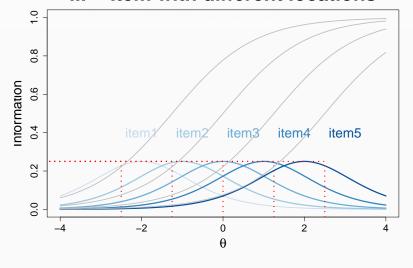

IRT

The more the item locations are spread along the trait, the merrier

Items should be as homogeneous as possible

CTT

Item Information Function Func

	item1	item2	item3	item4	item5
b	-2.50	-1.25	0.00	1.25	2.50

Test Information Function

1-PL

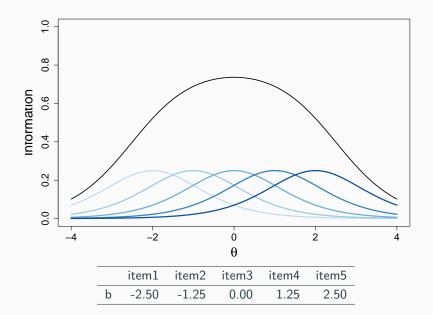

Test Information Function

Test Information Function

Measure of the precision with which the test assesses the latent trait:

$$I(\theta) = \sum I_i(\theta, b_i) =$$

Test Information Function

Test Information Function

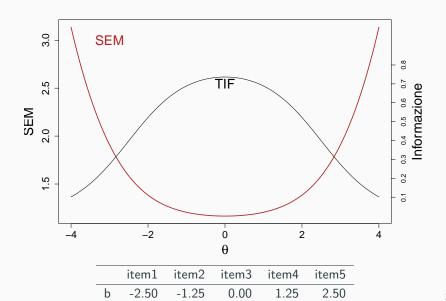

$$SEM(\theta) = \sqrt{\frac{1}{I(\theta)}} = \sqrt{\frac{1}{P_i(\theta, b_i)Q_i(\theta, b_i)}}$$

The higher the information, the lower the SEM

The lower the information, the higher the SEM

Differently from CTT \rightarrow the error of measuremt can vary for different levels of the latent trait

Test Information Function

2PL

Item Response Function

2PL

Item Response Function

$$P(x_{pi} = 1 | \theta_p, b_i, a_i) = \frac{\exp[a_i(\theta_p - b_i)]}{1 + \exp[a_i(\theta_p - b_i)]}$$

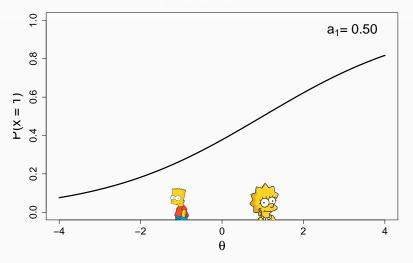

Dove:

 θ_p : Ability of the person (i.e., latent trait level of the person)

 b_i ; difficulty of item i (location of the item on the latent trait) ightarrow

 a_i : Discrimination of the item o ability of the item to tell apart subjects with different levels of the latent trait

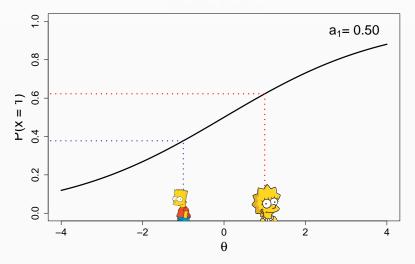

Item Response Function

Item 1 ($a_1 = 0.50$):

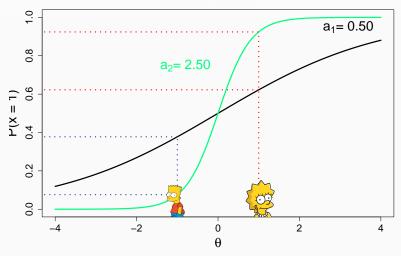

$$2 + 2 = ?$$

Item Response Function

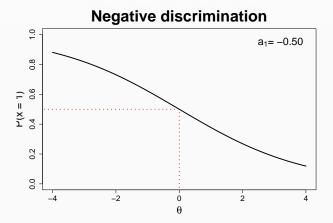

Item 1 ($a_1 = 0.50$):

$$2 + 2 = ?$$

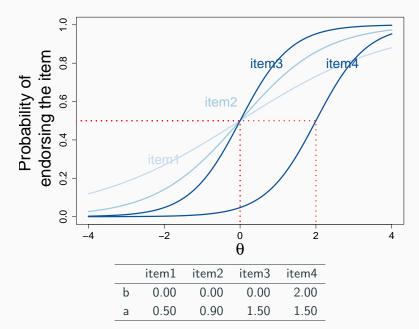

Item 1 (
$$a_1 = 0.50$$
): $2 + 2 = ?$

Item 2 (
$$a_2 = 2.50$$
): $5 + 14 = ?$

The higher the level of the latent trait... the lower the probability of responding correctly!

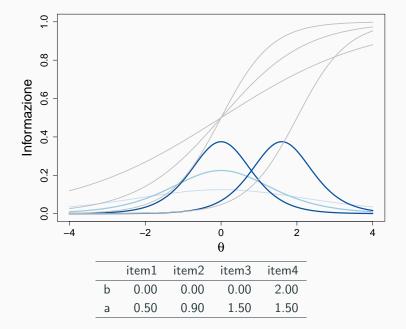

2PL

Item Information Function

$$I_i(\theta, b_i, a_i) = a_i^2 P_i(\theta, b_i, a_i) Q_i(\theta, b_i, a_i)$$

 $Q_i = 1 - P_i(\theta, b_i, a_i)$ is the probability of giving the incorrect response

2PL

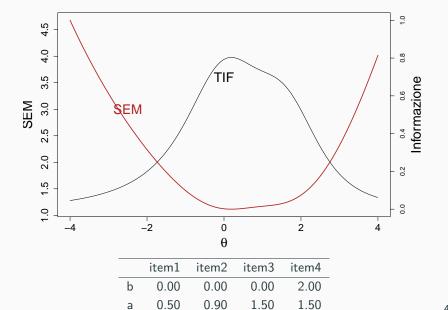

$$I(\theta) = \sum I_i(\theta, b_i, a_i)$$

Test Information Function

$$SEM(\theta) = \sqrt{\frac{1}{I(\theta)}} = \sqrt{\frac{1}{a^2 P_i(\theta, b_i) Q_i(\theta, b_i)}}$$

Test Information Function

3PL

3PL

Item Response Function

The lower asymptote is moved upward by adding a third item parameter, the pseudo-guessing (c_i) :

$$P(x_{pi} = 1 | \theta_p, b_i, a_i) = c_i + (1 - c_i) \frac{\exp[a_i(\theta_p - b_i)]}{1 + \exp[a_i(\theta_p - b_i)]}$$

 θ_p : Ability of the person (i.e., latent trait level of the person)

 b_i ; difficulty of item i (location of the item on the latent trait) ightarrow

 a_i : Discrimination of the item o ability of the item to tell apart subjects with different levels of the latent trait

 c_i : pseudo-guessing of item $i \to \text{probability}$ of giving the correct response even if the latent trait approaches $-\infty$

Item 1:
$$b_1=0$$
, $a_1=1.4$ e $c_1=0.2$, Item 2: $b_1=0$, $a_1=1.4$ e $c_1=0.3$ (item 2)

The probability of responding correctly is approximately c (0.20, 0.30) for low levels of the latent trait

Item Response Function

The probability of responding correctly when $\theta_p = b_i$ is higher than .50 $(P(x_{pi} = 1) = c + (1 - c)/2)$

In multiple-choice items \rightarrow subjects with low levels of the latent trait might try to guess the correct response

If there k response options that are all equally plausible, then $c\cong \frac{1}{k}$

WARNING

Assumption: All the response options are equally plausible

3PL

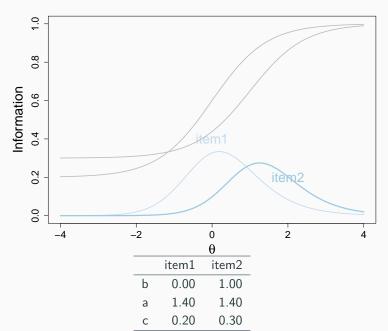

Item Information Function

$$I_i(\theta, b_i, a_i, c_i) = a^2 \frac{P_i(\theta, b_i, a_i, c_i)}{Q_i(\theta, b_i, a_i, c_i)} \left[\frac{P_i(\theta, b_i, a_i, c_i) - c_i}{1 - c_i} \right]$$

The higher the guessing, the lower the IIF

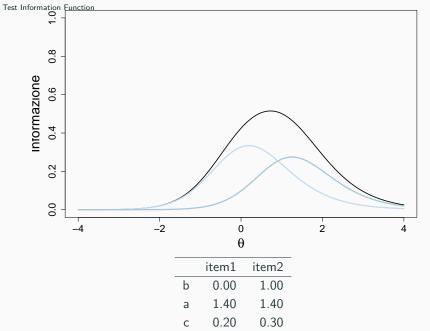

$$Q_i = 1 - P_i(\theta, b_i, a_i, c_i)$$
 è la probabilità di osservare una risposta errata

3PL

$$I(\theta) = \sum I_i(\theta, b_i, a_i, c_i)$$

$$SEM(\theta) = \sqrt{\frac{1}{I(\theta)}} = \sqrt{\frac{1}{a^2 P_i(\theta, b_i, a_i, c_i) Q_i(\theta, b_i, a_i, c_i)}}$$

4PL

4PL

Item Response Function

Lower the upper asymptote by adding a careless error parameter

$$P(x_{pi} = 1 | \theta_p, b_i.a_i) = c_i + (d_i - c_i) \frac{\exp[a_i(\theta_p - b_i)]}{1 + \exp[a_i(\theta_p - b_i)]}$$

Dove:

 θ_p : Ability of the person (i.e., latent trait level of the person)

 b_i , a_i , c_i ; Difficulty, discrimination, and pseduo-guessing of item i

 d_i : careless-error, probability of endorsing the item when the latent trait approaches $+\infty$

The lower then value of d_i , the lower the probability that a person with high level of the latent trait gives the correct response to item i

Item 1: b = 0, a = 1.4, c = 0.20, d = .9

Item 2: b = 0, a = 1.4, c = 0.30, d = .7

61

Relazione tra i modelli

- ullet Constraining the d_i parameters of all items to be 1 o from 4-PL to 3-PL
- Constraining the c_i parameters of all items to be 0 ightarrow from 3-PL to 2-PL
- ullet Constraining the a_i parameters of all items to be 1 o from 2-PL to 1_PL

Formally, the Rasch model and the 1-PL are the same model

IRT

Fit of the **models** to the data
The model that fit better the data
is chosen

Rasch

Fit of the data to the **model**The data are modified as long as they don't fit to the model

Relazione tra i modelli

All models are wrong...

The model can be chosen

- A priori:
 - Theoretical considerations
 - Item characteristics
- A posteriori:
 - Estimation of all the IRT models
 - Model comparison

Comparative fit indexes

- ullet -2loglikelihood
 ightarrow nested models only
- Akaike's Information Criterion (AIC)
- Bayesian Information Criterion (BIC)

It is the difference between the LogLikelihood of two nested models (multiplied by -2).

The significance of the difference between the LogLikelihood can be tested considering a χ^2 distribution with degrees of freedom equal to the difference in the degrees of freedom of the two nested models:

- Significant difference: The most complex model is the best one
- Non significant difference: The simplest model is the best one

AIC and BIC are entropy indexes \rightarrow the lower the better

AIC penalizes most complex models regardless of the sample size

$$AIC = -2logLik + 2p$$

BIC penalizes most complex models also accounting for the sample size

$$BIC = -2logLik + p \cdot log(N)$$
